

Backend Developer Technical Challenge

Overview

Build a Ruby on Rails application that models a media catalog and exposes a public API endpoint.

Domain

The application manages the following types of content:

- Movie
- TV Show
- Season
- Episode

Each content has the following mandatory attributes:

- `title`
- `original_title`
- `year`

A Season belongs to a TV Show.

An Episode belongs to a Season.

Seasons and Episodes have a number representing their position (for example, Season 1 or Episode 3).

The application also supports lists of content.

A list can contain any type of content.

Each list defines the order of its items.

API

Implement a public endpoint that returns the contents of a list.

The endpoint must:

- return the contents in the defined order;
- support pagination;
- accept an optional `content_type` parameter to return only contents of the specified type while preserving the order.

The endpoint does not require authentication.

The response format is your choice.

Deliverables

Please include:

- the Rails application;
- database migrations;
- a README describing:
 - how to run the application;
 - any assumptions you made while implementing the solution.

If you encounter ambiguous or unspecified requirements, make the assumptions you consider appropriate and document them in the README.
